Contents

- 2.1 Binary Search
- 2.2 Mergesort
- 2.3 The Divide-and-Conquer Approach
- 2.4 Quicksort (Partition Exchange Sort)

Appendix B. Solving Recurrence Equations

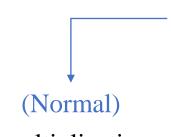

- 2.5 Strassen's Matrix Multiplication Algorithm
- 2.6 Arithmetic with Large Integers
- 2.7 Determining Thresholds
- 2.8 When Not to Use Divide-and-Conquer

- Matrix Multiplication Algorithm
 - Recall that Algorithm 1.4 multiplies two matrices
 - strictly according to the definition of matrix multiplication.
 - time complexity: $T(n) = n^3 \in \Theta(n^3)$.
 - Is it possible to design an efficient algorithm
 - whose time complexity is better than $\Theta(n^3)$?
 - Strassen published an algorithm (in 1969)
 - whose time complexity is better than cubic
 - in terms of both *multiplication* and *additions/subtractions*.

8 multiplications

4 additions

$$\begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \times \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix}$$

$$m_1 = (a_{11} + a_{22})(b_{11} + b_{22})$$

$$m_2 = (a_{21} + a_{22})b_{11}$$

$$m_3 = a_{11}(b_{12} - b_{22})$$

$$m_4 = a_{22}(b_{21} - b_{11})$$

$$m_5 = (a_{11} + a_{12})b_{22}$$

$$m_6 = (a_{21} - a_{11})(b_{11} + b_{12})$$

$$m_7 = (a_{12} - a_{22})(b_{21} + b_{22})$$

(Strassen's)

7 multiplications

18 additions/subtractions

$$C = \begin{bmatrix} m_1 + m_4 - m_5 + m_7 & m_3 + m_5 \\ m_2 + m_4 & m_1 + m_3 - m_2 + m_6 \end{bmatrix} -$$

- Pertaining the Strassen's Method to Larger Matrices
 - that are each *divided* into *four submatrices*.

$$M_1 = (A_{11} + A_{22})(B_{11} + B_{22})$$

$$M_2 = (A_{21} + A_{22})B_{11}$$

•••

$$C = \begin{bmatrix} M_1 + M_4 - M_5 + M_7 & M_3 + M_5 \\ M_2 + M_4 & M_1 + M_3 - M_2 + M_6 \end{bmatrix}$$

$$\begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix} = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 0 & 1 & 2 & 3 \\ 4 & 5 & 6 & 7 \end{bmatrix} \times \begin{bmatrix} 8 & 9 & 1 & 2 \\ 3 & 4 & 5 & 6 \\ 0 & 7 & 8 & 9 & 1 \\ 2 & 3 & 4 & 5 \end{bmatrix}$$

$$M_1 = (A_{11} + A_{22})(B_{11} + B_{22}) = \begin{bmatrix} 3 & 5 \\ 11 & 13 \end{bmatrix} \times \begin{bmatrix} 17 & 10 \\ 7 & 9 \end{bmatrix} = \begin{bmatrix} 86 & 75 \\ 278 & 227 \end{bmatrix}$$

$$M_2 = (A_{21} + A_{22})B_{11} = \begin{bmatrix} 11 & 4 \\ 10 & 12 \end{bmatrix} \times \begin{bmatrix} 8 & 9 \\ 3 & 4 \end{bmatrix} = \begin{bmatrix} 104 & 115 \\ 128 & 138 \end{bmatrix}$$

$$M_3 =$$

$$M_4 =$$

$$M_5 =$$

$$M_6 =$$

$$C = \begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix} = \begin{bmatrix} 43 & 53 & 54 & 37 \\ 123 & 149 & 130 & 93 \\ 95 & 110 & 44 & 41 \\ 103 & 125 & 111 & 79 \end{bmatrix}$$

$$M_7 =$$

ALGORITHM 2.8: Strassen (*pseudo-code*)

```
void strassen(int n, matrix_t A, matrix_t B, matrix_t& C) {
    if (n <= threshold) {</pre>
        compute C = A * B using the standard algorithm;
    else {
        partition A into four submatrices A11, A12, A21, A22;
        partition B into four submatrices B11, B12, B21, B22;
        compute C = A * B using Strassen's method;
            // example recursive call:
            // strassen(n/2, A11 + A22, B11 + B22, M1);
```

```
typedef vector<vector<int>> matrix t;
const int threshold = 1;
void print matrix(int n, matrix t M);
void resize(int n, matrix t& mat);
void madd(int n, matrix_t A, matrix_t B, matrix_t& C);
void msub(int n, matrix_t A, matrix_t B, matrix_t& C);
void mmult(int n, matrix_t A, matrix_t B, matrix_t &C);
void partition(int m, matrix_t M,
               matrix t& M11, matrix t& M12, matrix t& M21, matrix t& M22);
void combine(int m, matrix_t& M,
               matrix t M11, matrix t M12, matrix t M21, matrix t M22);
void strassen(int n, matrix_t A, matrix_t B, matrix_t &C);
```

```
matrix t A11, A12, A21, A22;
matrix t B11, B12, B21, B22;
matrix t C11, C12, C21, C22;
matrix_t M1, M2, M3, M4, M5, M6, M7;
matrix t L, R;
int m = n / 2;
resize(m, A11); resize(m, A12); resize(m, A21); resize(m, A22);
resize(m, B11); resize(m, B12); resize(m, B21); resize(m, B22);
resize(m, C11); resize(m, C12); resize(m, C21); resize(m, C22);
resize(m, C11); resize(m, C12); resize(m, C21); resize(m, C22);
resize(m, M1); resize(m, M2); resize(m, M3); resize(m, M4); resize(m, M5);
resize(m, M6); resize(m, M7); resize(m, L); resize(m, R);
```

```
void strassen(int n, matrix_t A, matrix_t B, matrix_t &C) {
    if (n <= threshold) {</pre>
        mmult(n, A, B, C);
    else {
        // Define local variables here.
        partition(m, A, A11, A12, A21, A22);
        partition(m, B, B11, B12, B21, B22);
        // Implement Strassen's Method Here.
        combine(m, C, C11, C12, C21, C22);
```

$m_1 = (a_{11} + a_{22})(b_{11} + b_{22})$	<pre>madd(m, A11, A22, L); madd(m, B11, B22, R); strassen(m, L, R, M1);</pre>
$m_2 = (a_{21} + a_{22})b_{11}$	<pre>madd(m, A21, A22, L); strassen(m, L, B11, M2);</pre>
$m_3 = a_{11}(b_{12} - b_{22})$	<pre>msub(m, B12, B22, R); strassen(m, A11, R, M3);</pre>
$m_4 = a_{22}(b_{21} - b_{11})$	<pre>msub(m, B21, B11, R); strassen(m, A22, R, M4);</pre>
$m_5 = (a_{11} + a_{12})b_{22}$	<pre>madd(m, A11, A12, L); strassen(m, L, B22, M5);</pre>

- Time Complexity of *Strassen's* (*multiplications*)
 - Basic Operation: one *elementary multiplication*.
 - Input Size: *n*, the *number of rows and columns* in the matrices.
 - For simplicity,
 - we keep dividing until n = 1 (threshold = 1).
 - Then, we can establish the recurrence:
 - T(n) = 7T(n/2), for n > 1, n is a power of 2.
 - T(1) = 1.

- Time Complexity of Strassen's (multiplications)
 - The recurrence is solved in Example B.2 in Appendix B:

$$T(n) = n^{\lg 7} \approx n^{2.81} \in \Theta(n^{2.81}).$$

$$T(n) = 7 \times T\left(\frac{n}{2}\right)$$

$$= 7^{2} \times T\left(\frac{n}{2^{2}}\right)$$

$$= \cdots$$

$$= 7^{k} \times T\left(\frac{n}{2^{k}}\right)$$

$$= 7^{k} \times T(1)$$

$$= 7^{k}$$

$$= 7^{k}$$

$$= 7^{k} \times T(1)$$

$$= 7^{k}$$

$$= 7^{k}$$

$$= 7^{k} \times T(1)$$

• We can also apply the *Master Theorem*.

- Time Complexity of *Strassen's* (additions/subtractions)
 - Basic Operation: one *elementary addition* or *subtraction*.
 - Input Size: *n*, the *number of rows and columns* in the matrices.
 - Again, for simplicity, we keep dividing until n = 1.
 - Then, we can establish the recurrence:
 - $T(n) = 7T(\frac{n}{2}) + 18(\frac{n}{2})^2$, for n > 1, n is a power of 2. elements들의 덧셈, 곱셈
 - T(1) = 0.
 - The recurrence is solved in Example B.20 in Appendix B:
 - $T(n) = 6n^{\lg 7} 6n^2 \in \Theta(n^{2.81})$
 - We can also apply the Master Theorem.

Comparing two algorithms:

	Standard Algorithm	Strassen's Algorithm
Multiplications	n^3	$n^{2.81}$
Additions/Subtractions	$n^3 - n^2$	$6n^{2.81} - 6n^2$

- What happen if n is not a power of 2?
 - Simply, *fill 0s to the matrices* to make the dimension a power of 2.

- How fast can we multiply two matrices?
 - There are some variants of Strassen's algorithm.
 - Some of them has more efficient complexity, to say, $\Theta(n^{2.38})$.
 - It is *provable* that the complexity requires at least $\Omega(n^2)$.
 - This is a *lower bound* of matrix multiplication *problem*.
 - Is it *possible* to design an efficient algorithm with $\Theta(n^2)$?
 - No one has ever developed an algorithm for it.
 - *No one* has ever *proved* that it is *not possible*.

T(n) = 11 * T(n/2) + O(1)

- Representation of Large Integers
 - Suppose that we need to do arithmetic operations on large integers
 - whose size *exceeds* the computer's *hardware capability*.
 - A straightforward way to represent a large integer is
 - to use an array of integers,
 - in which each array slot stores only one digit.

```
5 4 3 1 2 7
S[5] S[4] S[3] S[2] S[1] S[0]
```

- Data Type and Linear-Time Operations:
 - To represent both positive and negative integers
 - we need *only* reserve the *high-order* array slot for the *sign*.
 - 0 for positive, 1 for negative.
 - For convenience,
 - we assume that all the large integers are positive.

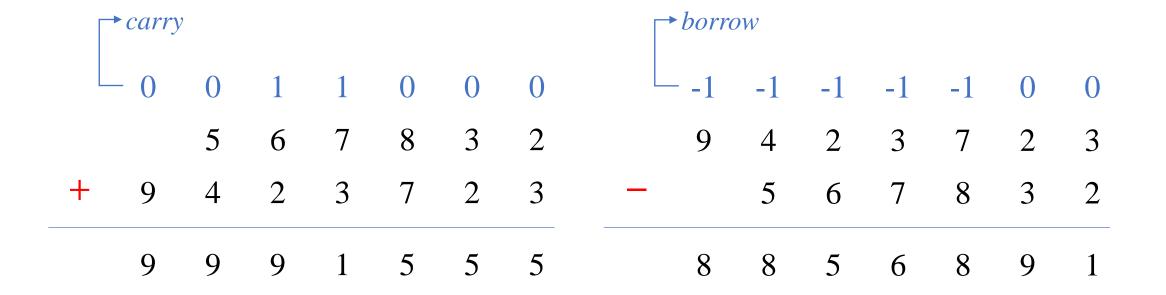

```
typedef vector<int> LargeInteger;
const int threshold = 1;
```

- Data Type and Linear-Time Operations:
 - Write linear-time algorithms for
 - addition & subtraction.
 - powered by exponent: $u \times 10^m$
 - divided by exponent: u divide 10^m
 - returns the *quotient* in integer division.
 - remainder by exponent: $u \operatorname{rem} 10^m$
 - return the remainder.

Addition & Subtraction

```
void roundup_carry(LargeInteger& v) {
    int carry = 0;
    for (int i = 0; i < v.size(); i++) {
        v[i] += carry;
        carry = v[i] / 10;
        v[i] = \frac{v[i] \% 10}{};
    if (carry != 0)
        v.push back(carry);
```

```
void ladd(LargeInteger a, LargeInteger b, LargeInteger& c) {
    c.resize(max(a.size(), b.size()));
    fill(c.begin(), c.end(), 0);
    for (int i = 0; i < c.size(); i++) {
        if (i < a.size()) c[i] += a[i];
        if (i < b.size()) c[i] += b[i];
    }
    roundup_carry(c);
}</pre>
```

- Multiplication of Large Integers:
 - A simple algorithm for multiplying large integers
 - has a *quadratic* time complexity: $\Theta(n^2)$.

		1	2	3
×			4	5
		5	10	15
+	4	8	12	
	4	13	22	15
	5	5	3	5

```
void lmult(LargeInteger a, LargeInteger b, LargeInteger& c) {
    c.resize(a.size() + b.size() - 1);
    fill(c.begin(), c.end(), 0);
    for (int i = 0; i < a.size(); i++)
        for (int j = 0; j < b.size(); j++)
        c[i + j] += a[i] * b[j];
    roundup_carry(c);
}</pre>
```

Operations with Exponents: Power, Divide, and Remainder

$$u = 567,832, m = 3$$

$$u \times 10^m$$

$$u = 567832000$$

$$u$$
 divide 10^m

$$u = 567832$$

$$u = 567832$$

```
void pow_by_exp(LargeInteger u, int m, LargeInteger &v) {
   if (u.size() == 0)
      v.resize(0);
   else {
      v.resize(u.size() + m);
      fill(v.begin(), v.end(), 0);
      copy(u.begin(), u.end(), v.begin() + m);
   }
}
```

```
void rem_by_exp(LargeInteger u, int m, LargeInteger &v) {
    if (u.size() == 0)
        v.resize(0);
    else {
        // Note that u.size() can be smaller than m.
        int k = m < u.size() ? m : u.size();</pre>
        v.resize(k);
        copy(u.begin(), u.begin() + k, v.begin());
        remove_leading_zeros(v);
```

- Designing an *Efficient* Multiplication Algorithm:
 - based on the Divide-and-Conquer approach
 - to *split* an *n*-digit integer into two integers of *approximately n/2* digits.

$$567,832 = 567 \times 10^{3} + 832$$

$$6 \text{ digits} \qquad 3 \text{ digits} \qquad 3 \text{ digits}$$

$$9,423,723 = 9,423 \times 10^{3} + 723$$

$$7 \text{ digits} \qquad 4 \text{ digits} \qquad 3 \text{ digits}$$

$$u = x \times 10^{m} + y$$

$$n \text{ digits} \qquad [n/2] \text{ digits} \qquad [n/2] \text{ digits}$$

The exponent m of 10 is given by $m = \lfloor n/2 \rfloor$

```
u = x \times 10^m + y
v = w \times 10^m + z
uv = (x \times 10^m + y)(w \times 10^m + z)
    = xw \times 10^{2m} + (xz + wy) \times 10^{m} + yz
567,832 \times 9,423,723 = (567 \times 10^3 + 832)(9,423 \times 10^3 + 723)
    = 567 \times 9,423 \times 10^{6} + (567 \times 723 + 9,423 \times 832) \times 10^{3} + 832 \times 723
    = 5,351,091,478,536
```

ALGORITHM 2.9: Large Integer Multiplication

```
large integer prod(large integer u, large integer v)
    large_integer x, y, w, z;
    int n, m;
    n = maximum(number of digits in u, number of digits in v);
    if (u == 0 || v == 0)
         return 0;
    else if (n <= threshold)</pre>
         return u × v obtained in the usual way;
    else {
         m = n / 2;
         x = u \text{ divide } 10^m; y = u \text{ rem } 10^m;
         w = v \operatorname{divide} 10^{m}; z = v \operatorname{rem} 10^{m};
         return prod(x, w) \times 10^{2m} + (prod(x, z) + prod(w, y)) \times 10^m + prod(y, z);
```

```
void prod(LargeInteger u, LargeInteger v, LargeInteger &r) {
    LargeInteger x, y, w, z;
    LargeInteger t1, t2, t3, t4, t5, t6, t7, t8;
    int n = max(u.size(), v.size());
    if (u.size() == 0 || v.size() == 0)
        r.resize(0);
    else if (n <= threshold)</pre>
        lmult(u, v, r);
    else {
        int m = n / 2;
        div_by_exp(u, m, x); rem_by_exp(u, m, y);
        div_by_exp(v, m, w); rem_by_exp(v, m, z);
        // t2 <- prod(x,w) * 10^(2*m)
        prod(x, w, t1); pow_by_exp(t1, 2 * m, t2);
        // t6 <- (prod(x,z)+prod(w,y)) * 10^m
        prod(x, z, t3); prod(w, y, t4); ladd(t3, t4, t5); pow_by_exp(t5, m, t6);
        // r < - t2 + t6 + prod(y, z)
        prod(y, z, t7); ladd(t2, t6, t8); ladd(t8, t7, r);
```

- Time Complexity of Algorithm 2.9 (*Worst-Case*)
 - Basic Operation: the *manipulation of one decimal digit* in a large integer
 - when adding, subtracting, or doing pow, div, and rem operations.
 - Input Size: *n*, the *number of digits* in each of the two integers.
 - The worst-case occurs when
 - both integers have *no digits equal to 0*,
 - because the recursion ends if and only if *threshold* is passed.
 - For simplicity, suppose that n is a power of 2.

- Time Complexity of Algorithm 2.9 (Worst-Case)
 - The operations of addition, subtraction, power, divide, and remainder
 - have linear time-complexities in terms of n, because m = n/2.
 - We can establish the recurrence equation:
 - W(n) = 4W(n/2) + cn, for n > s, n is a power of 2.
 - where *c* is a positive constant.
 - W(s) = 0, for $n \le s$.
 - Therefore,
 - $W(n) \in \Theta(n^{\log_2 4}) = \Theta(n^2)$. (Example B.25 in Appendix B)
 - We can apply the *Master Theorem*.

- What's happen?
 - Algorithm 2.9 is still quadratic: $\Theta(n^2)$
 - The algorithm does *four multiplications*
 - on integers with *half* as many digits as the original integers.
 - We should reduce the number of these multiplications.
 - to obtain an algorithm that is better than quadratic.

$$u = x \times 10^{m} + y$$

$$v = w \times 10^{m} + z$$

$$uv = xw \times 10^{2m} + (xz + wy) \times 10^{m} + yz$$

$$r = (x + y)(w + z) = xw + (xz + yw) + yz$$

$$(xz + yw) = r - (xw + yz)$$

$$uv = x\overline{w} \times 10^{2m} + ((x + y)(w + z) - (xw + yz)) \times 10^{m} + yz$$
three multiplications

ALGORITHM 2.10: Large Integer Multiplication 2

```
large_integer prod2(large_integer u, large_integer v)
    large_integer x, y, w, z, r, p, q;
    int n, m;
    n = maximum(number of digits in u, number of digits in v);
    if (u == 0 | | v == 0)
         return 0;
    else if (n <= threshold)</pre>
         return u × v obtained in the usual way;
    else {
         m = n / 2;
         x = u \text{ divide } 10^m; y = u \text{ rem } 10^m;
         w = v \text{ divide } 10^m; z = v \text{ rem } 10^m;
         r = prod2(x + y, w + z);
         p = prod2(x, w);
         q = prod2(y, z);
         return p \times 10^{2m} + (r - p - q) \times 10^{m} + q;
```

```
typedef long long largeint;
const int threshold = 1;
largeint karatsuba(largeint u, largeint v) {
    largeint x, y, w, z, p, q, r;
    int n = max(digits(u), digits(v));
    if (u == 0 || v == 0)
        return 0;
    else if (n <= threshold)</pre>
        return u * v;
    else {
        int m = n / 2;
        x = div by exp(u, m); y = rem by exp(u, m);
        w = div_by_exp(v, m); z = rem_by_exp(v, m);
        r = \frac{karatsuba}{x + y} (x + y);
        p = \frac{karatsuba}{x}(x, w);
        q = \frac{x}{x}
        return pow_by_exp(p, 2*m) + pow_by_exp(r-p-q, m) + q;
```

- Time Complexity of Algorithm 2.10 (Worst-Case)
 - If n is a power of 2, then x, y, w, and z all have n/2 digits.

$$-\frac{n}{2}$$
 <= digits in $x + y \le \frac{n}{2} + 1$.

$$-\frac{n}{2} <= \text{digits in } w + z \le \frac{n}{2} + 1.$$

n	х	у	x + y	Number of Digits in $x + y$
4	10	10	20	2 = n/2
4	99	99	198	3 = n/2 + 1
8	1000	1000	2000	4 = n/2
8	9999	9999	19,998	5 = n/2 + 1

- Time Complexity of Algorithm 2.10 (Worst-Case)
 - The input sizes for the given function calls:
 - prod2(x + y, w + z): $\frac{n}{2} \le \text{input size} \le \frac{n}{2} + 1$.
 - prod2(x, w): input size = $\frac{n}{2}$
 - prod2(y, z): input size = $\frac{n}{2}$
 - Therefore, W(n) satisfies
 - $-3W(\frac{n}{2}) + cn \le W(n) \le 3W(\frac{n}{2} + 1) + cn$, for n > s, n is a power of 2.
 - W(s) = 0, for $n \le s$.

- Time Complexity of Algorithm 2.10 (Worst-Case)
 - Owing to the left inequality in the recurrence and the Master Theorem:
 - $W(n) \in \Omega(n^{\log_2 3})$.
 - We can also show that
 - W(n) ∈ $O(n^{\log_2 3})$. (Refer to the textbook)
 - Therefore, combining these two results,
 - $W(n) \in \Theta(n^{\log_2 3})$.

- The Effect of *Threshold* Value
 - Recursion requires
 - a fair amount of overhead in terms of computer time.
 - Consider the problem of sorting *only eight keys*:
 - Which is the faster in terms of the *execution* time?
 - Recursive Mergesort: $\Theta(n \lg n)$ or Exchange Sort: $\Theta(n^2)$.
 - We need to develop a method that *determines for what value of n*
 - it is at least as fast to call an alternative algorithm as it is
 - to divide the instance further.

- Finding an *Optimal Threshold*:
 - An *optimal threshold value* of *n* is
 - an instance size such that for any smaller instance
 - it would be at least as fast to call the other algorithm as
 - it would be to divide the instance further,
 - and for any larger instance size
 - it would be faster to divide the instance again.

- Example: Mergesort & Exchange Sort
 - Recurrence of Mergesort (worst-case)
 - $W(n) = 2W(n/2) + 32n \mu s, W(1) = 0 \mu s$
 - Mergesort takes $W(n) = 32n \lg n \mu s$, where Exchange Sort takes $\frac{n(n-1)}{2} \mu s$.
 - Solving the inequality $\frac{n(n-1)}{2} < 32n \lg n$, the solution is n < 591.
 - Is it optimal to call Exchange Sort when n < 591
 - and to call Mergesort otherwise?
 - Note that this analysis is incorrect.
 - It only tells us that if we use Mergesort and keep dividing until n = 1,
 - then Exchange Sort is better for n < 591.

- The *Optimal Threshold* for Mergesort & Exchange Sort:
 - Suppose we modify Mergesort so that
 - Exchange Sort is called when $n \leq t$ for some threshold t.

•
$$W(n) = \begin{cases} \frac{n(n-1)}{2} \mu s, & \text{for } n \leq t \\ W(\left\lfloor \frac{n}{2} \right\rfloor) + W(\left\lceil \frac{n}{2} \right\rceil) + 32n \mu s, & \text{for } n > t \end{cases}$$

$$-W\left(\left\lfloor \frac{t}{2}\right\rfloor\right) + W\left(\left\lceil \frac{t}{2}\right\rceil\right) + 32t = \frac{t(t-1)}{2}$$

- Solving this equation, we can obtain t = 128. (Refer to the textbook)
- Therefore, we have
 - an *optimal threshold* value of 128.

2.8 When not to Use Divide-and-Conquer

- Avoid the Divide-and-Conquer in the following two cases:
 - 1. An instance of size n is divided into
 - two or more instances each almost size n.
 - It leads to an *exponential-time* algorithm.
 - 2. An instance of size n is divided into
 - almost *n* instances of size n/c, where *c* is a constant.
 - It leads to $n^{\Theta(\lg n)}$ algorithm.
 - Consider the following problems:
 - nth Fibonacci Term: Algorithm 1.6 (Recursive), 1.7 (Iterative)
 - Towers of Hanoi: *intrinsically* exponential algorithm.

- The n-th Fibonacci Number using Matrix Exponentiation
 - Can we calculate the n-th Fibonacci Number by *using matrix exponentiation*?
 - Use the following relation:

$$\begin{bmatrix} F_n \\ F_{n-1} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \times \begin{bmatrix} F_{n-1} \\ F_{n-2} \end{bmatrix}$$

$$-\begin{bmatrix} F_n \\ F_{n-1} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^n \times \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Any Questions?
